Integrating Transactionally Boosted Data Structures with STM Frameworks: A Case Study on Set

Ahmed Hassan, Roberto Palmieri, Binoy Ravindran
Virginia Tech

TRANSACT 2014
State of art

- Concurrent data structures are well optimized for high performance
  - E.g., Lazy linked-list, Lazy skip-list

What about Transactional data structures?
What about Transactional data structures?

- Software Transactional Memory (STM)?
  - Yes, but will lose performance

- Why?
  - For STM to be a general framework, data structures will suffer from false conflicts
False Conflict

- Example: Linked list (Insert “55”)
False Conflict

- Example: Linked list (Insert “55”)
  
- All “red” nodes are in the read-set
- “50” and “55” are in the write-set
- What if a concurrent transaction deletes “5”??

False Conflict
Solution for transactional data structures

- Solution: Transactional Boosting [Herlihy PPoPP08]
  - Convert highly concurrent data structures to transactional ones

- Other trials:
  - Early release, Elastic transactions, …
  - …but programmability is hampered
Motivation by examples

- Example of pure memory accesses to shared objects:

```java
Shared data: n1, n2

@Atomic
foo()
{
    n1++;
    n2++;
}
```

- Good:
  - Easy to program
  - Strong correctness and progress guarantees
Motivation by examples

- Example of pure memory accesses to shared data structure:

```java
Shared data: boostedSet

foo(x)
{
    boostedSet.add(x);
}
```

- Good:
  - Transactional support
  - Optimized for:
    - ensuring high performance
    - minimum false conflicts
Motivation by examples

Without an integrated support for allowing the coexistence of memory accesses and data structure accesses, boostedSet has to be a pure-STM set.

```java
@Atomic
foo()
{
    if(boostedSet.add(x))
        n1++;
    else
        n2++;
}
```
What we propose

- An integrated framework enabling:
  - Application programmers to exploit in the same transaction both STM accesses, as well as data structure accesses, without paying the cost of monitoring in the STM all memory accesses due to data structure operations (thus solving the problem of false conflicts)
  - Protocol designers to leverage the proposed software architecture for embedding new optimized data structures and STM protocols, in a way they can coexist in the same transaction
Design Choices

- As a guideline for implementing optimized transactional data structure, we adopt:
  - Optimistic Transactional Boosting (OTB) \[^{[PPoPP14]}\]

- Why OTB?
  - OTB is an optimistic methodology for converting concurrent data structures into transactional, and it is designed to support integration with STM
  - OTB uses the concepts of Validation, Commit, and Abort in the same way as several (optimistic) STM algorithms
  - OTB allows data structure-specific optimizations
### Lazy Vs Boosting Vs Optimistic Boosting

- **Comparison among:**
  - Concurrent Lazy data structures
  - Transactional data structures based on Original Boosting
  - Optimistic Transaction Boosting

</table>

- **OTB (Optimistic Transaction Boosting):**
  - Unmonitored Traversal
  - Validate Semantic read-set
  - Update Semantic read- and write-sets
  - Acquire Locks
  - Validate and Write
  - Release Locks
Design Choices

- As a basic framework for the integration, we use DEUCE

- Why DEUCE?
  - It is a Java STM framework with a simple interface
  - It already provides several STM algorithms
Our goals

- The design of our integrated solution has three main goals:
  - Keeping the simple programming interface of DEUCE
  - Allowing the integration between OTB data structures’ operations and memory reads/writes
  - Giving developers a simple API to plug-in their own OTB data structures and/or OTB-STM algorithms
The original DEUCE Framework:

- **Application**
  - `@Atomic`, `@Exclude`

- **DEUCE Runtime**
  - `@Atomic`, `@Exclude` (instrumented `foo`)

- **STM Algorithms**
  - `@Atomic`, `@Exclude` (STM Context)

- `foo`
Framework Design

- Our Additional Building Blocks:
  - Application
  - DEUCE Runtime
  - STM Algorithms
  - OTB Delegator
  - Transactional Data Structures
  - OTB Data Structures
  - STM Context
  - OTB-STM Context
Our case study

- In this paper we provide the integration of:
  - OTB Set, with
  - TL2, and
  - NOrec

- Other OTB data structures are presented in the technical report: "Optimistic Transactional Boosting", available at http://www.hyflow.org/pubs/ppopp_14_TR.pdf
OTB Set

- **Design:**
  - Semantic read-set: \( \text{pred}, \text{curr}, \text{operation} \)
  - Semantic write-set: \( \text{pred}, \text{curr}, \text{operation}, \text{newValue} \)

- **Correctness:**
  - Lazy (linearization): \( \text{pred} \) and \( \text{curr} \) are not deleted, and \( \text{pred} \) points to \( \text{curr} \)
  - STM (serialization): post-operation validation and commit validation

- **Integration:**
  - First Operation: \( \text{attachSet} \)
  - Validation: \( \text{validate-data}, \text{validate-data\&locks} \)
  - Commit: \( \text{preCommit}, \text{onCommit}, \text{postCommit} \)
Integration with NOrec

- Integration with NOrec is simple:
  - both OTB set and NOrec validate the read-set after each operation and perform a value-based validation at commit

- NOrec uses a coarse-grain lock, thus acquiring fine-grain semantic locks is not needed

- Validation:
  - onReadAccess: call OTB set’s validate-data
  - onOperationValidate: call NOrec’s validation

- Commit:
  - Do not call set’s preCommit and postCommit during transaction commit
  - Do not call set’s onAbort during transaction abort
Integration with TL2

- Integration with TL2 requires the acquisition of fine-grain semantic locks.
- Validation for OTB set is not value-based thus semantic locks are implemented as sequence locks.
- Validation
  - onReadAccess: call OTB set’s *validate-data&locks*
  - onOperationValidate: Do nothing with TL2
- Commit:
  - Call set’s *preCommit* and *postCommit* during transaction commit
  - Call set’s *onAbort* during transaction abort
Generalization

- All the differences between the integration of NOrec and TL2 are due to optimizations.

- We can generalize validation and commit for any STM algorithm (losing STM-specific optimizations, e.g. *validate-data* without checking locks).

- Further investigation on the generalization is considered as future work.
Performance Evaluation

- 48-core AMD Opteron machine
- 1400 MHz, 32 GB of memory, and 16KB L1 data cache.
- Average of 5 runs
- Warm-up phase of 2 seconds
- Execution phase of 5 seconds
Performance Evaluation

- Micro-Benchmarks – without pure memory reads/writes

Linked List - 512 nodes - 50% reads

Skip List - 4K nodes - 50% reads
Performance Evaluation

- Micro-Benchmarks – with pure memory reads/writes

Linked List - 512 nodes - 50% reads

Skip List - 4K nodes - 50% reads
Thanks!
